Abstract

As has been noted over the past ten years, “The wall between computer science and electrical engineering has kept the potential of embedded systems at bay. It is time to build a new scientific foundation with embedded systems design as the cornerstone, which will ensure a systematic and even-handed integration of the two fields.”^[1] In Baylor University’s School of Engineering & Computer Science, the Embedded Systems course in the Department of Computer Science, and the Embedded Systems Design course in the Department of Electrical and Computer Engineering have been offered independent of each other in the recent past. In the past year, however, this is beginning to change, with plans developing to combine the project portion of the two courses into one multi-disciplinary group project.

This paper will document the two courses – scope and sequence, as well as emphasis, equipment used, and delivery style – highlighting the need for a new and innovative approach at the systematic integration of software and hardware in the design and development of a multi-disciplinary group project. The beta test of this group project is occurring in the fall 2017 semester, with full first-time full-scale deployment during the spring 2018 semester. The results of this beta test will be discussed, and the lessons learned and planned modifications to the course will be considered.

Introduction

Over the past decade computer technology has become ubiquitous in our everyday lives. From digital camera, to the embedded systems that make up current vehicles, to automated highways, to home security systems, to automated household appliances, to robotic manufacturing, to integrated medical devices, to communications systems, even the term “embedded systems” has transcended previous definitions to now embody any “engineering artifact involving computation that is subject to physical constraints.”^[2] These are examples of some of the implementations of embedded systems design that are pushing existing technology to its limits, and going past many existing applications, and forcing us to rethink our process of teaching this subject.

In today’s automotive industry, as each new vehicle design receives yet another control unit, “software complexity escalates to the point that current development processes and tools can no longer ensure sufficiently reliable systems at affordable cost.”^[3] In this challenge lies an opportunity for the disciplines of computer science and electrical engineering to recognize the need for professionals who are able to bridge the divide between the disciplines and “integrate computation and physicality for the bottom up,” using non-traditional design methods.^{[4],[5]}

In Baylor University’s School of Engineering and Computer Science, two existing courses in embedded systems, each taught from differing perspectives, have joined to integrate software and hardware design and implementation in their group projects. This paper will discuss the existing courses, the design and development of multi-disciplinary group projects, implementation of these projects, and lessons learned in the beta test of this design.

ELC 4438, “Embedded Systems Design”

ELC 4438, “Embedded Systems Design,” has been taught as a required upper-level course in Baylor University’s Department of Electrical Engineering, currently deployed in a 4-hour semester course. Although the focus is mainly on the design and implementation of embedded computer systems using microcontrollers, sensors and data conversion devices, actuators, visual display devices, timers, and applications specific circuits, it also includes some software design using microprocessor cross-development systems and real-time operating system principles.

The main objective of the course is for students to learn to design and implement embedded computer solutions that meet specific system needs and/or requirements. In addition, during the course students are expected to:

1. Demonstrate understanding of embedded system design criteria
2. Design embedded systems and produce design rationale
3. Implement embedded system software solutions
4. Demonstrate understanding of real-time scheduling, priorities, and operating systems

5. Select hardware solutions that meet physical, computational, and interface requirements
6. Demonstrate a basic understanding of the Internet of Things (IoT) and distributed systems
7. Complete a final project that demonstrates the lifecycle of systems development

The means to evaluating these objectives was a combination of homework (10%), a series of labs (30%), two midterm exams (30%), and a final project (30%). The homework and labs, in particular, provided hands-on opportunities to apply what was learned, leading up to the final project.

Homework was assigned to cover topics including:

- SysTick: intended to familiarize students with the SysTick Timer and begin to think about how to use it to control time in the labs
- Digital Thermometer Design: intended to demonstrate knowledge and application of the design process
- TWIM Diagrams: application of Three Winding Induction Motors (TWIM) with respect to the temperature sensor
- Scheduling: application of various scheduling algorithms, dependencies, and the graphical representation of these schedules
- Project Idea Submittal: research and compilation of various group project ideas

The labs included a series of in-class demonstrations of the understanding and integration of:

- Lab 1: Introduction to the Atmel SAM4L XPlained Pro
- Lab 2: Atmel
- Lab 3: Serial I/O
- Lab 4: Design
- Lab 4: Implementation
- Lab 5: Stopwatch
- Lab 6: Event Driven Lab
- Lab 7: Review of C, Functions
- Lab 8: Static Scheduler
- Digital Thermometer Implementation
- Linux Lab
- BeagleBone Black Wireless (BBBw) Setup
- BBBw Flashlight Lab
- BBBw TMP36 Lab

CSI 4v96, “Embedded Systems”

CSI 4v96, “Embedded Systems,” is an upper-level computer science elective that was introduced in the fall of 2016. It is a variable-hour “Special Topics” course in the computer science curricula, currently deployed in a 3-hour semester course. Different than ELC 4438, the course introduces embedded systems from a computer science prospective using the BBBw embedded Linux platform. The course assumes mastery of systems programming, software design, algorithms, and a

variety of operating systems. However, the course also expects students to

- Review, understand, and apply basic circuits principles
- Understand and demonstrate the scheduling of hardware resources
- Demonstrate knowledge and application of hardware constraints when designing software for embedded systems
- Demonstrate understanding of discrete components, use of transistors and FETs as switches, interconnection/interface to logic gates, and analog-to-digital conversion
- Demonstrate application of control of BBBw GPIO pins through software
- Demonstrate application of cross-compilation and the Eclipse IDE
- Demonstrate understanding of bus communication
- Demonstrate understanding and application of the IoT using a variety of devices communicating through a variety of communication protocols

Evaluation of these objectives was conducted through a variety of Labs and Assignments (30%), two midterm exams (40%), and a final project (30%). The purpose of the labs and assignments, in particular, prepared students to apply what they had learned in the application of their final projects.

A series of homework assignments were assessed, including:

- Assignment (A)1: Compare and contrast several current microcontrollers/small board computers against a wide variety of performance characteristics
- A2: Implementation of a “die” object in Java Script, rolling the die 60,000 times, verifying the frequency distribution
- A2Extra Credit: Creation of a binary clock in Java Script
- A3: Circuits Exercises
- A4: IoT Literature Search
- A5: Use and application of the ThingSpeak API

The labs provided an evaluation of student’s understanding of what they had learned through a variety of software and hardware interfaces:

- Lab 1: Debian flashing and setup
- Lab 2: Wifi setup, update packages, install ntpdate, add user account (primary, instead of “root”)
- Lab 3: Updating packages
- Lab 4: JavaScript lab, access to BBBw as a local server
- Lab 5: TMP36 Sensor Lab
- Lab 6: TMP36 Sensor Lab, Part II
- Lab 7: LED Lab
- Lab 8: Digital I/O
- Lab 9: Analog I/O
- Lab 10: Apache Web Server

- Lab 11: TMP36 Web Pages
- Lab 12: Java Lab
- Lab 13: Virtualbox Eclipse Lab
- Lab 14: Java VM
- Lab 15: Switches and RGB LED
- Lab 16: Light Sensor
- Lab 17: ThingSpeak
- Lab 18: Bluetooth
- Lab 19: ADXL345 Accelerometer
- Lab 20: RFID Lab

Joint Group Project Design & Development

The multidisciplinary group project in CSI 4v96 and ELC 4438 began right after midterm. Students from CSI 4v96 met with ELC 4438 during the simultaneously-scheduled regular lecture period for both courses. Both classes were introduced to the project phase, where they would decide on projects, with an overview of the evaluation artifacts:

1. Project Documents: Statement of Work (SOW) iterations, hardware design, software design, progress reports, etc.
2. Project Presentation and Results
3. Project Report and Submittal
4. Final Project Code Submit to Git repository

These artifacts were weighted somewhat differently for the CS students and the ELC students, based on the varying objectives of the two courses.

The milestones for the project were presented:

- Beginning of project phase - October 17
- Team formation complete - October 19
- Initial SOW Submittal - October 23
- Formative Assessment of teams - November 7
- Project Team Final Presentations - November 28
- Final Report Due/Summative Assessment - December 8

Individual students were invited to present their project ideas in order to develop interest among the students. The final projects selected included:

- Group 1: Music Frequency Display using Bluetooth
- Group 2: Automated Clay Pigeon Shooter
- Group 3: Bear Copter
- Group 4: Musical Multi-Effects Pedal with Analog Control and LED display
- Group 5: Smart Room
- Group 6: Car LED Notification
- Group 7: Mouse Droid

CATME, the Comprehensive Assessment for Team-Member Effectiveness^{[6],[7]}, was used to build project teams and to conduct both the formative and summative peer assessments. In building the teams, the various criteria were weighted

(including a specific project preference for team members), with the highest weights being time availability, project motivation, project perspective, and project selection.

All teams submitted an initial SOW, and an iterative process was begun where project teams received feedback on the scope of their respective SOWs until a final SOW was determined.

For the remaining weeks in the semester, project teams worked on their projects, reporting status weekly to both instructors. Adjustments were made based on hardware availability and team evaluation of feasibility of project scope. Teams met twice a week in class, as well as outside of class as determined by each team. A formative assessment of team effectiveness was conducted using CATME Peer Assessment, and the results of this assessment were delivered to each student. Each student, using their team's assessment of their work, could make adjustments to their team roles and responsibilities, to afford a better summative assessment.

Final project presentations were conducted over two days, allowing each team roughly fifteen minutes to present their projects and submit their final documents. In many cases, a video-taped and/or live demonstration was conducted and reported during the final project presentation. Each team, based on their final presentation of results, could recover from minor hardware/software malfunctions by making an additional presentation before the last day of classes.

Team members were required to submit a summative peer assessment via CATME. The raw scores of each assessment were evaluated by instructors, with adjustments made based on the thoughtfulness of the assessment, and individual multipliers were applied to the group project grade for each team member.

Summary

Development of this multi-disciplinary group project methodology was developed through a series of design and development meetings. The methodology was tested in the fall of 2017 with the two classes' students participating. Effectiveness of these teams was assessed by the team members themselves and by the instructors, based on the quality of cross training performed within each team, quality of hardware design, quality of software design, effective communication of the project, and professionalism of the final project report.

The students involved in this experiment were invited to report on the effectiveness of the project, with respect to the course content (labs, assignments, exams, projects), the current course format (dates/times of class meetings), the selection of the small board computer selected for the deployment of the course, how final grades were determined, and the final project design. Many lessons were learned, and a collection of best practices were determined based on this student evaluation as

well as the instructors' assessment on the respective classes and the group projects.

Lessons learned include:

- Current labs provide an ample background to prepare students for the project
- Labs and assignments should continue at the current pace
- CSI 4v96 should be made a 4-hour course, concurrently scheduled with the ELC 4438 course, to afford more time for project work
- CSI 4v96 was perceived to be one of the top candidates for upper-level computer science elective courses (students recommend it be made a permanent course)
- The BBBw has limited online resources, when compared to other small board computers, but the availability of GPIO on the BBBw makes it a good hardware platform for future courses
- There was some confusion on team roles and responsibilities in the integration of the two courses for the group projects

Some of the adjustments that will be made to the two courses, and the multi-disciplinary group project teams, will include:

- Additional assessment of team members' roles and responsibilities will be formalized in individually evaluated assessments, for example, use of the jigsaw technique will be used to divide teams into common roles and responsibilities. Each team member will cross train their team mates on their area of expertise.
- The possibility of CSI 4v96 becoming a 4-hour course will be pursued
- The possibility of CSI 4v96 becoming a permanent course (instead of a variable-hour special topics course) will be evaluated based on department priorities and resources.
- The new Peer-to-Peer reporting function will be incorporated in future offerings.
- The CATME student training resources will be made mandatory modules for students, and will be assessed.

- The importance of team assessment will be formally included in the course, focusing on the importance of team building and team assessment.

Additional details of this group project experiment will be disseminated through the ASEE National Conference in Salt Lake City, Utah, on June 24-27, 2018.
